(54) Title: METABOTROPIC GABA_B RECEPTORS, RECEPTOR-SPECIFIC LIGANDS AND THEIR USES

(57) Abstract.

The present invention provides purified GABA_B receptors and receptor proteins derived from rat and human sources, as well as nucleic acids which encode such proteins. The proteins and nucleic acids of the invention share significant homology with the GABA_B receptor and the DNA encoding it as specifically disclosed herein. The invention moreover provides methods for isolating other members of the GABA_B receptor family using DNA cloning technology and probes derived from the sequences provided herein, as well as novel members of the GABA_B receptor family isolated by such methods. Furthermore, the invention relates to the use of GABA_B receptors and receptor proteins and cells transformed with a gene encoding a GABA_B receptor protein in a method for identifying and characterising compounds which modulate the activity of the GABA_B receptor, such as GABA_B receptor agonists and antagonists, which may be useful as pharmacological agents for the treatment of disorders associated with the central and peripheral nervous systems.

METABOTROPIC GABA_B RECEPTORS, RECEPTOR-SPECIFIC LIGANDS AND THEIR USES

The present invention relates to nucleic acids encoding proteins of the GABA_B receptor family, as well as proteins encoded thereby and the use of such proteins for the development of pharmacological agents.

Gamma-aminobutyric acid (GABA) is the major inhibitory neurotransmitter found in the brain and peripheral nervous system. Receptors for GABA have been divided into two subfamilies, the GABA_A and GABA_B receptors. Of these, GABA_A receptors are involved in fast inhibitory signal transmission, whilst GABA_B receptors appear to be involved in modulation of neurotransmission. Pre-synaptic GABA_B receptors influence the release of neurotransmitters and neuropeptides such as GABA, glutamate, noradrenaline, dopamine, 5-hydroxytryptamine, substance P, cholecystokinin and somatostatin, while post-synaptic GABA_B receptors are coupled to potassium channels via G proteins and mediate late inhibitory post-synaptic potentials (IPSPs). The effect of the activation of both subtypes of the GABA_B receptor is to modulate synaptic transmission.

GABA_B receptors are located throughout the central and peripheral nervous systems (see Ong and Kerr, *Life Sciences*, (1990) **46**, 1489-1501; Bowery *et al.*, *Drug Res.* (1992) **42**(1), 2a, 215-223), and are thus involved in the regulation of a wide variety of neurally-controlled physiological responses, from memory and learning to muscle contraction. This makes the GABA_B receptor a target for pharmaceutical agents intended to treat central and peripheral neural disorders, and indeed a variety of GABA_B agonists and antagonists are known and have been proposed for use in therapy (Bittiger *et al.*, in *GABA: Receptors, Transporters and Metabolism*, Tanaka, C., and Bowery, N.G. (Eds). Birkhäuser Verlag Basel/Switzerland (1996), 297-305; Bittiger *et al.*, *Trends Pharmacol. Sci.*, **14**, 391-394, 1993; Froestl *et al.*, *J. Med. Chem.*, **38**, 3297-3312, 1995; Froestl *et al.*, *Ibid.*, 3313-3331). For example, in Alzheimer's disease and other dementias such as Age Associated Memory Impairment and Multi Infarct Dementia, loss of cognitive function is associated with reduced levels of a number of neurotransmitters in the brain. In particular, a deficit in L-glutamate is expected to cause a major loss of cognitive functions, since L-glutamate appears to be crucially involved in the processes underlying memory formation and learning. GABA acts directly at many synapses to reduce the release of L-glutamate by acting on GABA_B hetero-receptors. Thus, GABA_B receptor antagonists are indicated for the treatment of dementias,

and indeed have been shown to improve cognitive functions in animal studies. In addition, GABA_B receptor antagonists are expected to be active in psychiatric and neurological disorders such as depression, anxiety and epilepsy (Bittiger *et al.*, 1993, 1996, Op. Cit.; Froestl *et al.*, 1995, Op. Cit.). GABA_B receptor agonists are known as antispastic agents, and in peripheral nervous system applications, agonists are expected to be beneficial in bronchial inflammation, asthma and coughing (Bertrand *et al.*, Am. J. Resp. Crit. Care Med. 149, A900, 1994). GABA is moreover associated with activity in the intestine, the cardiovascular system, gall and urinary bladders, and a variety of other tissues (Ong and Kerr, Op. Cit.).

GABA action in each of the above cases is known to be mediated by GABA_B receptors, making the receptors targets for pharmacological agents designed to treat a number of disorders.

Despite the advanced state of molecular biology and protein purification technology, and the evident desirability of obtaining a purified GABA_B receptor for pharmacological studies, the GABA_B receptor previously has not been cloned or purified to homogeneity. A previous report of its partial purification (Nakayasu *et al.*, J. Biol. Chem., 268, 8658-8664, 1993) appears to have been inaccurate, relating to an 80 kDa protein, which we now know to be too small. In order to be able to clone the GABA_B receptor, we have developed a number of GABA_B receptor-specific ligands. By expression cloning using one such highly selective GABA_B receptor ligand labelled to high specific radioactivity, we have now cloned different GABA_B receptors from rat and human sources, sequenced them and expressed the respective recombinant receptors in mammalian cell culture.

Summary of the Invention

The present invention provides purified GABA_B receptors and GABA_B receptor proteins, as well as nucleic acids which encode such proteins. The proteins and nucleic acids of the invention share significant homology with the GABA_B receptors and the DNAs encoding them as specifically disclosed herein. In particular, there are provided two GABA_B receptor proteins designated GABA_BR1a and GABA_BR1b which are distinct variants of GABA_B isolated from rat. The respective cDNA and derived amino acid sequences are set forth in SEQ ID Nos. 1, 2, and 5, 6, respectively. Furthermore, there are provided two human GABA_B receptor clones termed GABA_BR1a/b (representing a partial receptor clone) and GABA_BR1b (representing a full-length receptor clone) isolated from human sources.

- 3 -

The respective cDNA and derived amino acid sequences are set forth in SEQ ID Nos. 3, 4, and 7, 8, respectively.

The GABA_B receptors and GABA_B receptor proteins of the invention show specific binding to one or more of the selective GABA_B receptor antagonists of Formula I and Formula II:

I

II

The invention accordingly provides the compounds of Formula I and Formula II. Moreover, binding of these selective GABA_B receptor antagonists may be competed with other selective GABA_B receptor agonists or antagonists, such as the compound of Formula III and Formula IV:

III

CGP 35348

IV

The invention moreover provides methods for isolating other members of the GABA_B receptor family using DNA cloning technology and probes derived from the sequences provided herein, as well as novel members of the GABA_B receptor family isolated by such methods.

Furthermore, the invention relates to the use of GABA_B receptors and GABA_B receptor proteins and cells transformed with a gene encoding such a GABA_B receptor or receptor protein in a method for identifying and characterising compounds which modulate the activity of the GABA_B receptor(s), such as GABA_B receptor agonists and antagonists, which may be useful as pharmacological agents for the treatment of disorders associated with the central and peripheral nervous systems. In particular, GABA_B receptor antagonists can e.g. be useful as cognition enhancers, nootropics, antidepressants and anxiolytics for the treatment of cerebral insufficiency, depression, anxiety, epilepsy of the petit mal type, schizophrenia and myopia, whereas GABA_B receptor agonists can e.g. be useful in the treatment of disorders such as spasticity, trigeminal neuralgia, asthma, cough, emesis, ulcers, urinary incontinence and cocaine addiction.

Brief Description of the Figures

Figure 1a depicts the expression of the recombinant GABA_BR1a receptor in COS1 cells. Membranes from rat cortex membranes (lane 1) and COS1 cells transfected with the GABA_BR1a rat-cDNA (lanes 2 and 3) are labelled with the photoaffinity ligand [¹²⁵I]CGP 71872. Autoradiography of a 6% SDS gel with 25µg protein loaded per lane is shown. Lanes 1 and 2: Specific binding with 0.6nM [¹²⁵I]CGP 71872. Lane 3: Control experiment where specific binding with 0.6nM [¹²⁵I]CGP 71872 is competed with 1µM of unlabeled CGP 54626A (an antagonist specific for GABA_B receptors). The apparent molecular weight of native and recombinant GABA_B receptors are estimated from gel mobilities relative to those

of SDS-PAGE standards (BioRad). Figure 1b additionally shows the results for COS1 cells transfected with the GABA_BR1b rat-cDNA (lane 3).

Figure 2 shows the inhibition of [¹²⁵I]CGP 64213 binding to GABA_B receptors in membranes from rat cerebral cortex (open symbols) and recombinant GABA_BR1a receptors in membranes from COS 1 cells (closed symbols) by the GABA_B receptor antagonists CGP 54626A (●), CGP 64213 (▲) and CGP 35348 (■).

Figure 3 shows the inhibition of [¹²⁵I]CGP 64213 binding to GABA_B receptors in membranes from rat cerebral cortex (open symbols) and recombinant GABA_BR1a receptors in membranes from COS 1 cells (closed symbols) by the GABA_B receptor agonists GABA (●), L-baclofen (▲) and APPA 3-(aminopropyl-phosphinic acid) (■).

Figure 4 shows photoaffinity crosslinking of GABA_B receptor proteins. Cell membranes of the tissues indicated are photoaffinity-labelled with [¹²⁵I]CGP71872 and subjected to SDS-PAGE and autoradiography. *a, b*, Selectivity of the photoaffinity ligand [¹²⁵I]CGP71872. *a*, Differential distribution of GABA_B receptor variants of 130K and 100K in tissues of the nervous system. [¹²⁵I]CGP71872 binding is inhibited by addition of 1 μM of CGP54626A, a selective GABA_B receptor antagonist. *b*, Competition of [¹²⁵I]CGP71872 labelling by different ligands. Incubation of membrane extracts with the photoaffinity ligand is carried out in the presence of competitor substances at the concentrations indicated. *c*, GABA_B receptors are N-glycosylated. Photoaffinity-labelled rat cortex cell membranes are incubated with 0.4 units N-glycosidase F or 0.6 milliunits O-glycosidase (Boehringer Mannheim). *d*, Photolabelling of GABA_B receptors from different species. Brain tissues from the species indicated are labelled as described hereinbelow. In the case of *Drosophila melanogaster* and *Haemonchus contortus* whole animals are analysed.

Figure 5 shows the results of assays concerning pharmacological properties of native and recombinant GABA_B receptors. GABA_BR1a mediates inhibition of adenylate cyclase. HEK293 cells stably expressing GABA_BR1a are treated with 20 μM forskolin (Fsk) to stimulate cAMP formation (100%). Fsk induced cAMP accumulation is reduced significantly ($2P < 0.001$; Dunnett's *t*-test) upon simultaneous addition of 300 μM L-baclofen. The effect of L-baclofen is antagonised in the presence of 10 μM CGP54626A. Preincubation of the cells

with 10 ng/ml pertussis toxin (PTX) for 15-20 h completely abolishes the effect of L-baclofen. No L-baclofen response is observed in non-transfected HEK293 cells (insert). Bars represent mean values \pm S.E.M. of at least three independent experiments performed in quadruplicate.

Detailed Description of the Invention

The invention relates to purified GABA_B receptors and GABA_B receptor proteins, nucleic acids coding therefore and various applications thereof. Before the present invention, the GABA_B receptor has not been available in purified form, but only as crude membrane preparations. For the first time, the present invention enables the production of different but related GABA_B receptors in a substantially purified form, by means of recombinant DNA technology. In general, it is expected that such proteins in glycosylated form will have an observed molecular weight of between 100 and 130 kDa, whereas the unglycosylated forms will have an observed molecular weight of between 90 and 110 kDa, respectively.

GABA_B receptors according to the invention are G-protein coupled modulators of neurotransmitter activity which are responsive to GABA. They may be defined by binding to labelled ligands which are selective for GABA_B receptors, in particular [¹²⁵I]CGP 62413 and [¹²⁵I]CGP 71872. Functional studies are moreover possible in which a recombinant GABA_B receptor is expressed in cell systems containing G-proteins and effectors such as ionic channels which can be activated by GABA and GABA_B receptor agonists.

Proteins according to the invention may be defined electrophysiologically in transgenic or knockout animals, for example in terms of their responsiveness in assays for the GABA_B receptor(s) which are known in the art, such as the measurement of late IPSPs (inhibitory post-synaptic potentials), paired-pulse inhibition or (-)-baclofen-induced depression of field EPSPs (excitatory post-synaptic potentials). GABA_B receptors are responsible for the observation of IPSPs as a result of indirect coupling to potassium channels in neurons, so established agonists and antagonists of GABA_B receptors may be used to determine the presence of GABA_B receptors in neuronal preparations by assaying for their effect on IPSPs.

Advantageously, however, GABA_B receptor proteins according to the invention are assessed by their susceptibility to CGP62413 and CGP71872 as measured by paired-pulse widening of field EPSPs. Both said compounds abolish paired-pulse widening normally associated with GABA_B receptors, since they are effective GABA_B autoreceptor antagonists.

Preferably, therefore, the activation of GABA_B receptor proteins according to the invention is specifically inhibited by CGP64213 and CGP71872. Examples of specific inhibition by these compounds are set out hereinbelow.

As used herein, the term "GABA_B receptor(s)" refers to the proteins whose sequences are substantially those set forth in SEQ ID Nos. 2 and 8, while the term "GABA_B receptor proteins" includes derivatives and variants such as e.g. splice variants thereof which are related structurally and/or functionally to the GABA_B receptor(s). Preferred GABA_B receptor proteins according to the invention are e.g. those set forth in SEQ ID Nos. 4 and 6, and share at least one common structural determinant with the GABA_B receptors having the amino acid sequences set forth in SEQ ID Nos. 2 and 8, respectively. "Common structural determinant" means that the derivative in question comprises at least one structural feature of the GABA_B receptors set out in SEQ ID Nos. 2 and 8. Structural features includes possession of an epitope or antigenic site that is capable of cross-reacting with antibodies raised against a naturally occurring or denatured GABA_B receptor polypeptide or fragment thereof, possession of amino acid sequence identity with the GABA_B receptor(s) and features having common a structure/function relationship. Thus the GABA_B receptor proteins as provided by the present invention include amino acid mutants, glycosylation variants and other covalent derivatives of the GABA_B receptor(s) which retain the physiological and/or physical properties of the GABA_B receptor(s).

Further included within the scope of the term "GABA_B receptor proteins" are naturally occurring variants of the GABA_B receptor(s) found within a particular species, preferably a mammal. Such a variant may be encoded by a related gene of the same gene family, by an allelic variant of a particular gene, or represent an alternative splicing variant of the GABA_B receptor gene. Variants according to the invention have the same basic function as the GABA_B receptor(s), but may possess divergent characteristics consistent with their nature as variants. For example, it is expected that the GABA_B receptors are members of a family of GABA_B receptor proteins, the isolation and characterisation of which is enabled for the first time by the present invention. Different members of the GABA_B receptor family may be expected to have different activity profiles, possibly according to differences in their tissue-specific localisation and role in modulating neuronal signalling.

Moreover, the present invention enables the isolation and characterisation of further GABA_B receptors, GABA_B receptor proteins and GABA_B receptor protein-encoding nucleic acids from any species, including man. The provision of sequence data enables the person skilled in the art to apply standard hybridisation methodology, as is known in the art and set

out by way of example hereinbelow, to isolate any desired GABA_B receptor-encoding nucleic acid.

The invention further comprises derivatives of the GABA_B receptor(s), which retain at least one common structural determinant of the GABA_B receptor(s). For example, derivatives include molecules wherein the protein of the invention is covalently modified by substitution, chemical, enzymatic, or other appropriate means with a moiety other than a naturally occurring amino acid. Such a moiety may be a detectable moiety such as an enzyme or a radioisotope.

Derivatives which retain common structural determinants can be fragments of the GABA_B receptor(s). Fragments of the GABA_B receptor(s) comprise individual domains thereof, as well as smaller polypeptides derived from the domains. Preferably, smaller polypeptides derived from the GABA_B receptor(s) according to the invention define a single feature which is characteristic of the GABA_B receptor(s). Fragments may in theory be almost any size, as long as they retain one feature of the GABA_B receptor(s). Preferably, fragments will be between 5 and 600 amino acids in length. Longer fragments are regarded as truncations of the full-length GABA_B receptor(s) and generally encompassed by the term "GABA_B receptor(s)". Preferably, said fragments retain the functional activity of the GABA_B receptor(s). Such fragments may be produced by persons skilled in the art, using conventional techniques, by removing amino acid residues from the GABA_B receptor proteins of the invention which are not essential for a particular functional aspect of the GABA_B receptor proteins. Determination of functional aspects of a GABA_B receptor protein may be made employing pharmacological or electrophysiological assays as herein described, and particularly by assays which monitor the ability of the GABA_B receptor protein to bind GABA or a GABA mimic, or to couple to G proteins.

Derivatives of the GABA_B receptor(s) also comprise mutants thereof, which may contain amino acid deletions, additions or substitutions, subject to the requirement to maintain at least one feature characteristic of the GABA_B receptor(s). Thus, conservative amino acid substitutions may be made substantially without altering the nature of the GABA_B receptor(s). Substitutions and further deletions may moreover be made to the fragments of GABA_B receptor proteins comprised by the invention. GABA_B receptor protein mutants may be produced from a DNA encoding a GABA_B receptor protein which has been subjected to *in vitro* mutagenesis resulting e.g. in an addition, exchange and/or deletion of one or more amino acid encoding triplets. For example, substitutional, deletional or insertional variants of the GABA_B receptor(s) can be prepared by recombinant methods and

screened for immuno- or physiological crossreactivity with the native forms of the GABA_B receptor(s).

Mutations may be performed by any method known to those of skill in the art. Preferred, however, is site-directed mutagenesis of a nucleic acid sequence encoding the polypeptide of interest. A number of methods for site-directed mutagenesis are known in the art, from methods employing single-stranded phage such as M13 to PCR-based techniques (see "PCR Protocols: A guide to methods and applications", M.A. Innis, D.H. Gelfand, J.J. Sninsky, T.J. White (eds.). Academic Press, New York, 1990). Preferably, the commercially available Altered Site II Mutagenesis System (Promega) may be employed, according to the directions given by the manufacturer.

The fragments, mutants and other derivatives of the GABA_B receptor(s) preferably retain substantial homology with the GABA_B receptor(s). As used herein, "homology" means that the two entities share sufficient characteristics for the skilled person to determine that they are similar in origin and function. Preferably, homology is used to refer to sequence identity. Thus, the derivatives of the GABA_B receptor(s) preferably retain substantial sequence identity with the sequences set forth in SEQ ID Nos. 2 and 8, respectively.

"Substantial homology", where homology indicates sequence identity, means more than 30% sequence identity, preferably more than 65% sequence identity and most preferably a sequence identity of 80% or more.

According to a further aspect of the present invention, there are provided nucleic acids encoding GABA_B receptors and GABA_B receptor proteins (SEQ ID Nos. 1, 7, and 3, 5, respectively). In addition to being useful for the production of recombinant GABA_B receptors and receptor proteins, these nucleic acids are also useful as probes, thus readily enabling those skilled in the art to identify and/or isolate nucleic acids encoding further members of the GABA_B receptor family and variants thereof as set forth hereinbefore.

In another aspect, the invention provides nucleic acid sequences that are complementary to, or are capable of hybridising to, nucleic acid sequences encoding the GABA_B receptors or receptor proteins. Preferably, such nucleic acids are capable of hybridising under high or moderate stringency, as defined hereinbelow.

Furthermore, nucleic acids according to the invention are useful in a method determining the presence of a GABA_B receptor- or receptor protein-specific nucleic acid, said method comprising hybridising the DNA (or RNA) encoding (or complementary to) the

GABA_B receptor or receptor protein to test sample nucleic acid and determining the presence of the GABA_B receptor- or receptor protein-specific nucleic acid.

The invention also provides a method for amplifying a nucleic acid test sample comprising priming a nucleic acid polymerase (chain) reaction with nucleic acid (DNA or RNA) encoding a GABA_B receptor or receptor protein, or a nucleic acid complementary thereto.

Isolated GABA_B receptor- or receptor protein-specific nucleic acids include nucleic acids that are free from at least one contaminant nucleic acid with which they are ordinarily associated in the natural source of GABA_B receptor- or receptor protein-specific nucleic acids or in crude nucleic acid preparations, such as DNA libraries and the like. Isolated nucleic acids thus are present in other than in the form or setting in which they are found in nature. However, isolated GABA_B receptor and receptor protein encoding nucleic acids include GABA_B receptor- and receptor protein-specific nucleic acids in ordinarily GABA_B receptor- or receptor protein-expressing cells, where the nucleic acids are in a chromosomal location different from that of natural cells or are otherwise flanked by different DNA sequences than those found in nature.

In accordance with the present invention, there are provided isolated nucleic acids, e.g. DNAs or RNAs, encoding GABA_B receptors and GABA_B receptor proteins, particularly mammalian GABA_B receptors and receptor proteins, such as e.g. human and rat GABA_B receptors and receptor proteins, or fragments thereof. In particular, the invention provides DNA molecules encoding human and rat GABA_B receptors or receptor proteins, or fragments thereof. By definition, such a DNA comprises a coding single stranded DNA, a double stranded DNA consisting of said coding DNA and complementary DNA thereto, or this complementary (single stranded) DNA itself. Exemplary nucleic acids encoding GABA_B receptors and GABA_B receptor proteins are represented in SEQ ID Nos. 1, 7, and 3, 5, respectively.

The preferred sequences encoding GABA_B receptors and receptor proteins are those having substantially the same nucleotide sequence as the coding sequences in SEQ ID Nos. 1, 3, 5 and 7, with the nucleic acids having the same sequence as the coding sequences in SEQ ID Nos. 1, 3, 5 and 7 being most preferred. As used herein, nucleotide sequences which are substantially the same share at least about 90 % identity. However, in the case of splice variants having e.g. an additional exon sequence homology may be lower.

The nucleic acids of the invention, whether used as probes or otherwise, are preferably substantially homologous to the sequences encoding the GABA_B receptors or receptor proteins as shown in SEQ ID No. 1, 3, 5 and 7. The terms "substantially" and "homologous" are used as hereinbefore defined with reference to the GABA_B receptor polypeptides.

Preferably, nucleic acids according to the invention are fragments of the GABA_B receptor- or receptor protein-encoding sequences, or derivatives thereof as hereinbefore defined in relation to polypeptides. Fragments of the nucleic acid sequences of a few nucleotides in length, preferably 5 to 150 nucleotides in length, are especially useful as probes.

Exemplary nucleic acids can alternatively be characterised as those nucleotide sequences which encode a GABA_B receptor or receptor protein as hereinbefore defined and hybridise to the DNA sequences set forth in SEQ ID Nos. 1, 3, 5 and/or 7, or a selected fragment of said DNA sequences. Preferred are such sequences encoding GABA_B receptors or receptor proteins which hybridise under high-stringency conditions to the sequences of SEQ ID Nos. 1, 3, 5 and/or 7.

Stringency of hybridisation refers to conditions under which polynucleic acids hybrids are stable. Such conditions are evident to those of ordinary skill in the field. As known to those of skill in the art, the stability of hybrids is reflected in the melting temperature (T_m) of the hybrid which decreases approximately by 1 to 1.5°C with every 1% decrease in sequence homology. In general, the stability of a hybrid is a function of sodium ion concentration and temperature. Typically, the hybridisation reaction is performed under conditions of higher stringency, followed by washes of varying stringency.

As used herein, high stringency refers to conditions that permit hybridisation of only those nucleic acid sequences that form stable hybrids in 1 M Na⁺ at 65-68 °C. High stringency conditions can be provided, for example, by hybridisation in an aqueous solution containing 6x SSC, 5x Denhardt's, 1 % SDS (sodium dodecyl sulphate), 0.1 sodium pyrophosphate and 0.1 mg/ml denatured salmon sperm DNA as non specific competitor. Following hybridisation, high stringency washing may be done in several steps, with a final wash (about 30 min) at the hybridisation temperature in 0.2 - 0.1x SSC, 0.1 % SDS.

Moderate stringency refers to conditions equivalent to hybridisation in the above described solution but at about 60-62°C. In that case the final wash is performed at the hybridisation temperature in 1x SSC, 0.1 % SDS.

Low stringency refers to conditions equivalent to hybridisation in the above described solution at about 50-52°C. In that case, the final wash is performed at the hybridisation temperature in 2x SSC, 0.1 % SDS.

It is understood that these conditions may be adapted and duplicated using a variety of buffers, e.g. formamide-based buffers, and temperatures. Denhardt's solution and SSC are well known to those of skill in the art as are other suitable hybridisation buffers (see, e.g. Sambrook, *et al.*, eds. (1989) *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory Press, New York or Ausubel, *et al.*, eds. (1990) *Current Protocols in Molecular Biology*, John Wiley & Sons, Inc.). In particular, the skilled person will understand that the stringency of hybridisation conditions may be varied by altering a number of parameters, primarily the salt concentration and the temperature, and that the conditions obtained are a result of the combined effect of all such parameters. Optimal hybridisation conditions have to be determined empirically, as the length and the GC content of the probe also play a role.

Nucleic acids according to the invention may moreover be designed to have quite different sequences from those of nucleic acids encoding GABA_B receptors or receptor proteins as derived from natural sources, through exploitation of the degeneracy of the amino acid code. In most cases, a plurality of nucleotide triplets may be used to encode a given amino acid. Thus, an almost limitless number of nucleic acids which encode identical GABA_B receptors or receptor proteins may be designed. Those which most differ from the sequence of the naturally occurring nucleic acid may be so different as to be unable to hybridise therewith. The invention thus specifically encompasses any nucleic acid which encodes a GABA_B receptor or GABA_B receptor protein as hereinbefore defined. Preferred are all nucleic acids which encode the sequences of the GABA_B receptors and receptor proteins set forth in SEQ ID Nos. 2, 8, and 4, 6, respectively.

Given the guidance provided herein, the nucleic acids of the invention are obtainable according to methods well known in the art. For example, a DNA of the invention is obtainable by chemical synthesis, using polymerase chain reaction (PCR) or by screening a genomic library or a suitable cDNA library prepared from a source believed to possess GABA_B receptor or receptor protein and to express it at a detectable level.

Chemical methods for synthesis of a nucleic acid of interest are known in the art and include triester, phosphite, phosphoramidite and H-phosphonate methods, PCR and other autopriming methods as well as oligonucleotide synthesis on solid supports. These methods may be used if the entire nucleic acid sequence of the nucleic acid is known, or the

sequence of the nucleic acid complementary to the coding strand is available. Alternatively, if the target amino acid sequence is known, one may infer potential nucleic acid sequences using known and preferred coding residues for each amino acid residue.

An alternative means to isolate a gene encoding GABA_B receptor or receptor protein is to use PCR technology as described e.g. in section 14 of Sambrook et al., 1989. This method requires the use of oligonucleotide probes that will hybridise to a GABA_B receptor- or receptor protein-specific nucleic acid.

A nucleic acid encoding a GABA_B receptor or receptor protein can be isolated by screening suitable cDNA or genomic libraries under suitable hybridisation conditions with a probe, i.e. a nucleic acid disclosed herein including oligonucleotides derivable from the sequences set forth in SEQ ID Nos. 1, 3, 5 and 7. Suitable libraries are commercially available or can be prepared e.g. from cell lines, tissue samples, and the like. Libraries are screened with probes or analytical tools designed to identify the gene of interest or the protein encoded by it. For cDNA expression libraries suitable means include monoclonal or polyclonal antibodies that recognise and specifically bind to the GABA_B receptor or GABA_B receptor protein; oligonucleotides of about 20 to 80 bases in length that encode known or suspected GABA_B receptor- or receptor protein-specific cDNA from the same or different species; and/or complementary or homologous cDNAs or fragments thereof that encode the same or a hybridising gene. Appropriate probes for screening genomic DNA libraries include, but are not limited to oligonucleotides, cDNAs or fragments thereof that encode the same or hybridising DNA; and/or homologous genomic DNAs or fragments thereof.

Particularly preferred screening techniques include the hybridisation of a test sample of DNA (cDNA or genomic library) with a GABA_B receptor- or receptor protein-specific cDNA (SEQ ID Nos. 1, 3, 5, 7) under suitable hybridisation conditions. Either the full length or fragments of the GABA_B receptor- or receptor protein-specific cDNA can be used as probes. Such screening is initially carried out under low-stringency conditions. Low stringency conditions are as hereinbefore defined, but may be varied by adjusting the temperature and ionic strength of the hybridisation solution. For example, suitable conditions comprise hybridisation at a temperature between 40°C and 60°C in 0.5M NaH₂PO₄, pH 7.2, 7% sodium dodecyl sulphate (SDS), 1% bovine serum albumin, 1mM EDTA, with a washing step at 50°C or less in 2 x standard saline citrate (SSC, 20 x SSC contains 3M sodium chloride, 0.3M sodium citrate, pH 7.0), 0.1% SDS. Preferably, hybridisation conditions will be selected which allow the identification of nucleotide sequences having at least 40% sequence homology with respect to the probe. Similar homology screening techniques

useful for the identification and isolation of additional cDNAs and genes of the GABA_B-receptor gene family are described in United States Patent Number 5,202,257, incorporated herein by reference.

After low stringency hybridisation has been used to identify cDNA or genomic clones having a substantial similarity with the probe sequence, these clones are then subjected to moderate to high stringency conditions in order to identify those clones having particularly high level of homology with respect to the probe sequence. Further examples of high stringency conditions comprise a hybridisation temperature of about 60°C to 68°C using the above mentioned hybridisation solution. Washing conditions comprise 0.5 x SSC, 0.1% SDS or less at a temperature of about 65°C or less.

In view of the identification of GABA_B receptor- and receptor protein-specific cDNAs according to the invention, the compiled sequence information can be used to design a set of degenerate oligonucleotide primer sequences from the regions most conserved among members of the gene family. A mixture of such oligonucleotide primers can be used in the polymerase chain reaction (PCR) to amplify cDNAs or genomic segments from genes related to the already isolated GABA_B receptor- and receptor protein-specific cDNAs.

Subsequently, these segments can serve as probes for identifying further full-length cDNA clones using high stringency hybridisation conditions. Alternatively, antibodies derived against the GABA_B receptors or GABA_B receptor protein provided by the present invention can be used to purify and sequence related GABA_B receptors and receptor proteins also recognised by the antibodies.

Screening of libraries in order to isolate nucleic acids according to the invention may moreover be performed by expression screening. Such methodology is known to those skilled in the art, for example as set out in Sambrook *et al.* (Op. Cit.), but essentially comprises the incorporation of nucleic acid clones into expression vectors which are then screened using a ligand specific for the desired protein product. GABA_B receptor- or receptor protein-specific ligands may be antibodies, as described hereinbelow, or specific GABA antagonists or agonists. Especially preferred are compounds such as CGP 64213, described hereinbelow.

As used herein, an oligonucleotide probe is preferably a single-stranded DNA or RNA that has a sequence of nucleotides that includes between 10 and 50, preferably between 15 and 30 and most preferably at least about 20 contiguous bases that are the same as (or the complement of) an equivalent or greater number of contiguous bases as set forth in

SEQ ID Nos. 1, 3, 5 and 7. The nucleic acid sequences selected as probes should be of sufficient length and sufficiently unambiguous so that false positive results are minimised. The nucleotide sequences are usually based on conserved or highly homologous nucleotide sequences or regions of the GABA_B receptor or receptor protein. The nucleic acids used as probes may be degenerate at one or more positions. The use of degenerate oligonucleotides may be of particular importance where a library is screened from a species in which preferential codon usage in that species is not known.

Preferred regions from which to construct probes include 5' and/or 3' coding sequences, sequences predicted to encode ligand binding sites, and the like. For example, either the full-length cDNA clones disclosed herein or fragments thereof can be used as probes. Preferably, nucleic acid probes of the invention are labelled with suitable label means for ready detection upon hybridisation. For example, a suitable label means is a radiolabel. The preferred method of labelling a DNA fragment is by incorporating $\alpha^{32}\text{P}$ dATP with the Klenow fragment of DNA polymerase in a random priming reaction, as is well known in the art. Oligonucleotides are usually end-labelled with $\gamma^{32}\text{P}$ -labelled ATP and polynucleotide kinase. However, other methods (e.g. non-radioactive) may also be used to label the fragment or oligonucleotide, including e.g. enzyme labelling, fluorescent labelling with suitable fluorophores and biotinylation.

After screening the library, for example with a portion of DNA including substantially the entire GABA_B receptor- or receptor protein-encoding sequence or a suitable oligonucleotide based on a portion of said DNA, positive clones are identified by detecting a hybridisation signal; the identified clones are characterised by restriction enzyme mapping and/or DNA sequence analysis, and then examined, for example by comparison with the sequences set forth herein, to ascertain whether they include DNA encoding a complete GABA_B receptor or receptor protein (i.e., if they include translation initiation and termination codons). If the selected clones are incomplete, they may be used to rescreen the same or a different library to obtain overlapping clones. If the library is genomic, then the overlapping clones may include exons and introns. If the library is a cDNA library, then the overlapping clones will include an open reading frame. In both instances, complete clones may be identified by comparison with the DNAs and deduced amino acid sequences provided herein.

In order to detect any abnormality of endogenous GABA_B receptor or receptor protein, genetic screening may be carried out using the nucleotide sequences of the invention as

hybridisation probes. Also, based on the nucleic acid sequences provided herein antisense-type therapeutic agents may be designed. In particular reference thereto, it is to be noted that antisense oligonucleotides are based on oligonucleotide probes as hereinbefore defined, and included within the definition thereof. Such oligonucleotides, especially but not only when intended for use as antisense therapeutic agents, may comprise modifications to the oligonucleotide, for example by incorporation of unnatural nucleotide analogues and modifications to natural oligonucleotides. For example, the oligonucleotides may encompass an altered backbone, for example in the form of a phosphorothioate, modifications such as 2'-O-Methyl modifications, or may be in the form of peptide nucleic acids.

It is envisaged that the nucleic acids of the invention can be readily modified by nucleotide substitution, nucleotide deletion, nucleotide insertion or inversion of a nucleotide stretch, and any combination thereof. Such mutants can be used e.g. to produce a GABA_B receptor or receptor protein mutant that has an amino acid sequence differing from the GABA_B receptor or receptor protein sequences as disclosed herein or as found in nature. Mutagenesis may be predetermined (site-specific) or random. A mutation which is not a silent mutation must not place sequences out of reading frames and preferably will not create complementary regions that could hybridise to produce secondary mRNA structure such as loops or hairpins.

In still another aspect of the invention, the nucleic acids are DNA molecules and further comprise a replicable vector comprising the nucleic acid encoding the GABA_B receptor or receptor protein operably linked to control sequences recognised by a host transformed by the vector. As used herein, vector (or plasmid) refers to discrete elements that are used to introduce heterologous DNA into cells for either expression or replication thereof. Selection and use of such vehicles is a routine matter for the person of ordinary skill in the art and is described, for example, in Sambrook *et al.*, (1989) *Molecular Cloning: A Laboratory Manual*, Second Edition, Cold Spring Harbor Laboratory Press. Many vectors are available, and selection of appropriate vector will depend on the intended use of the vector, i.e. whether it is to be used for DNA amplification or for DNA expression, the size of the DNA to be inserted into the vector, and the host cell to be transformed with the vector. Each vector contains various components depending on its function (amplification of DNA or expression of DNA) and the host cell for which it is compatible. The vector components generally include, but are not limited to, one or more of the following: an origin of replication,

one or more marker genes, an enhancer element, a promoter, a transcription termination sequence and a signal sequence.

Advantageously, a eukaryotic expression vector encoding a GABA_B receptor or receptor protein will comprise a locus control region (LCR). LCRs are capable of directing high-level integration site independent expression of transgenes integrated into host cell chromatin, which is of importance especially where the GABA_B receptor or receptor protein gene is to be expressed in the context of a permanently-transfected eukaryotic cell line in which chromosomal integration of the vector has occurred, in vectors designed for gene therapy applications or in transgenic animals.

Suitable vectors for expression in eukaryotic host cells, including yeast, fungi, insect, plant, animal, human, or nucleated cells from other multicellular organisms, will also contain sequences necessary for the termination of transcription and for stabilising the mRNA. Such sequences are commonly available from the 5' and 3' untranslated regions of eukaryotic or viral DNAs or cDNAs.

Furthermore the invention provides host cells transformed with such a vector and a method of using a nucleic acid encoding a GABA_B receptor or receptor protein according to the invention to produce such a GABA_B receptor or receptor protein, comprising expressing a GABA_B receptor- or receptor protein-specific nucleic acid in a culture of the transformed host cells and, if desired, recovering the GABA_B receptor or receptor protein from the host cell culture. In accordance with another embodiment of the present invention, there are provided cells containing the above-described nucleic acids. Such host cells such as prokaryote, yeast and higher eukaryote cells may be used for replicating DNA and producing GABA_B receptor or receptor protein. Suitable prokaryotes include eubacteria, such as Gram-negative or Gram-positive organisms, such as *E. coli*, e.g. *E. coli* K-12 strains DH5a, MC1061/P3 and HB101, or *Bacilli*. Further hosts suitable for GABA_B receptor protein encoding vectors include eukaryotic microbes such as filamentous fungi or yeast, e.g. *Saccharomyces cerevisiae*. Higher eukaryotic cells include insect and vertebrate cells, particularly mammalian cells. In recent years propagation of vertebrate cells in culture (tissue culture) has become a routine procedure. Examples of useful mammalian host cell lines are epithelial or fibroblastic cell lines such as Chinese hamster ovary (CHO) cells, COS cells, NIH 3T3 cells, HeLa cells or HEK293 cells. The host cells referred to in this disclosure comprise cells in *in vitro* culture as well as cells that are within a host animal.

DNA may be stably incorporated into cells or may be transiently expressed using methods known in the art, such as those detailed in Sambrook *et al.*, Op. Cit., or Ausubel *et al.*, (1990) Current Protocols in Molecular Biology, John Wiley & Sons, Inc.

The polypeptides according to the invention can advantageously be expressed in insect cell systems, including whole insects. Insect cell lines suitable for use in the method of the invention include, in principle, any lepidopteran cell which is capable of being transformed with an expression vector and expressing heterologous proteins encoded thereby. In particular, use of the Sf cell lines, such as the *Spodoptera frugiperda* cell line IPBL-SF-21 AE (Vaughn *et al.*, (1977) In Vitro, 13, 213-217) is preferred. The derivative cell line Sf9 is particularly preferred. However, other cell lines, such as *Tricoplusia ni* 368 (Kurstack and Marmorosch, (1976) Invertebrate Tissue Culture Applications in Medicine, Biology and Agriculture. Academic Press, New York, USA) may be employed. These cell lines, as well as other insect cell lines suitable for use in the invention, are commercially available (e.g. from Stratagene, La Jolla, CA, USA).

Expression vectors suitable for use in the invention include all vectors which are capable of expressing foreign proteins in insect cell lines. In general, vectors which are useful in mammalian and other eukaryotic cells are also applicable to insect cell culture. Baculovirus vectors, specifically intended for insect cell culture, are especially preferred and are widely obtainable commercially (e.g. from Invitrogen and Clontech). Other virus vectors capable of infecting insect cells are known, such as Sindbis virus (Hahn *et al.*, (1992) PNAS (USA) 89, 2679-2683). The baculovirus vector of choice (reviewed by Miller (1988) Ann. Rev. Microbiol. 42, 177-199) is *Autographa californica* multiple nuclear polyhedrosis virus, AcMNPV.

Nucleic acids and/or proteins according to the invention may be used in methods for screening compounds of mixtures of compounds which are potential modulators of GABA_B receptors, and thus potential pharmacological agents. For example, cells transformed with a gene encoding a GABA_B receptor or receptor protein can be used in a cell-based screening assay, in which the response of the cell to the agents being tested is monitored. The response may be in the form of the activation of a reporter gene, a measurable pharmacological or electrophysiological change, or the like. Alternatively, purified GABA_B receptors or receptor proteins according to the invention can be used in *in vitro* assays to screen for modulators of GABA_B receptor activity.

Likewise, compounds which are capable of modulating the expression of the GABA_B receptor genes, thus regulating GABA_B receptor activity, can be screened for using an expression system in which a test gene (which may be one of the GABA_B receptor genes itself) is operably linked to the control sequences normally associated with the GABA_B receptor gene.

The invention moreover includes compounds identified by such screening assays and the use of such compounds for the treatment of conditions which are susceptible to treatment by GABA_B receptor modulation as exemplified hereinbefore.

In accordance with yet another embodiment of the present invention, there are provided antibodies specifically recognising and binding to one or more of the GABA_B receptors or receptor proteins of the invention. For example, such antibodies can be generated against the GABA_B receptors having the amino acid sequences set forth in SEQ ID Nos. 2 and 8. Alternatively, GABA_B receptor proteins as set forth in SEQ ID Nos. 4 and 6 or GABA_B receptor protein fragments (which may also be synthesised by *in vitro* methods) are fused (by recombinant expression or an *in vitro* peptidyl bond) to an immunogenic polypeptide and this fusion polypeptide, in turn, is used to raise antibodies against a GABA_B receptor protein epitope.

Anti-GABA_B receptor or receptor protein antibodies may be recovered from the serum of immunised animals. Monoclonal antibodies may be prepared from cells from immunised animals in the conventional manner.

The antibodies of the invention are useful for studying GABA_B receptor protein localisation, screening of an expression library to identify nucleic acids encoding GABA_B receptors or receptor proteins or the structure of functional domains, as well as for the purification of GABA_B receptors or receptor proteins, and the like.

Antibodies according to the invention may be whole antibodies of natural classes, such as IgE and IgM antibodies, but are preferably IgG antibodies. Moreover, the invention includes antibody fragments, such as Fab, F(ab')₂, Fv and ScFv. Small fragments, such as Fv and ScFv, possess advantageous properties for diagnostic and therapeutic applications on account of their small size and consequent superior tissue distribution.

The antibodies according to the invention may be used in diagnostic and therapeutic applications. Accordingly, they may be altered antibodies comprising an effector protein such as a toxin or a label. Especially preferred are labels which allow the imaging of the distribution of the antibody *in vivo*. Such labels may be radioactive labels or radioopaque labels, such as metal particles, which are readily visualisable within an organism. Moreover,

they may be fluorescent labels or other labels which are visualisable on tissue samples removed from organisms.

Recombinant DNA technology may be used to improve the antibodies of the invention. Thus, chimeric antibodies may be constructed in order to decrease the immunogenicity thereof in diagnostic or therapeutic applications. Moreover, immunogenicity may be minimised by humanising the antibodies by CDR grafting [see European Patent Application 0 239 400 (Winter)] and, optionally, framework modification [see EP 0 239 400 and Riechmann *et al.*, Nature 332, 323-327, 1988].

Antibodies according to the invention may be obtained from animal serum, or, in the case of monoclonal antibodies or fragments thereof, produced in cell culture. Recombinant DNA technology may be used to produce the antibodies according to established procedure, in bacterial or preferably mammalian cell culture. The selected cell culture system preferably secretes the antibody product.

Therefore, the present invention includes a process for the production of an antibody according to the invention comprising culturing a host, e.g. *E. coli* or a mammalian cell, which has been transformed with a hybrid vector comprising an expression cassette comprising a promoter operably linked to a first DNA sequence encoding a signal peptide linked in the proper reading frame to a second DNA sequence encoding said protein, and isolating said protein.

The invention further concerns hybridoma cells secreting the monoclonal antibodies of the invention. The preferred hybridoma cells of the invention are genetically stable, secrete monoclonal antibodies of the invention of the desired specificity and can be activated from deep-frozen cultures by thawing and recloning.

The invention also concerns a process for the preparation of a hybridoma cell line secreting monoclonal antibodies directed to a GABA_B receptor or receptor protein, characterised in that a suitable mammal, for example a Balb/c mouse, is immunised with purified GABA_B receptor or receptor protein, an antigenic carrier containing purified GABA_B receptor or receptor protein or with cells bearing GABA_B receptor or receptor protein, antibody-producing cells of the immunised mammal are fused with cells of a suitable myeloma cell line, the hybrid cells obtained in the fusion are cloned, and cell clones secreting the desired antibodies are selected. For example spleen cells of Balb/c mice immunised with cells bearing GABA_B receptor or receptor protein are fused with cells of the myeloma cell line PA1 or the myeloma cell line Sp2/0-Ag14, the obtained hybrid cells are screened for secretion of the desired antibodies, and positive hybridoma cells are cloned.

The invention also concerns recombinant DNAs comprising an insert coding for a heavy chain variable domain and/or for a light chain variable domain of antibodies directed to the extracellular domain of GABA_B receptor or receptor protein as described hereinbefore. By definition such DNAs comprise coding single stranded DNAs, double stranded DNAs consisting of said coding DNAs and of complementary DNAs thereto, or these complementary (single stranded) DNAs themselves.

The invention also provides a transgenic non-human mammal which has been modified to modulate the expression of endogenous GABA_B receptor or receptor protein. Preferably, the transgenic non-human mammal is a transgenic mouse. For example, therefore, a transgenic mouse may be designed in which GABA_B receptor or receptor protein production is greatly reduced or eliminated, according to procedures established in the art (Mansour *et al.*, Nature 336, 348-352, 1988). Alternatively, the transgenic mouse of the invention may express elevated levels of GABA_B receptor or receptor protein, or may be subject to regulation of GABA_B receptor or receptor protein expression in a developmentally or tissue-specific manner, or via control by exogenous agents. Study of such an animal provides insights into the importance of the GABA_B receptors and receptor proteins *in vivo*.

The invention is further described hereinbelow, for the purposes of illustration only, in the following Examples.

Example 1

Synthesis of ligand CGP64213

The radioligand [¹²⁵I]CGP 64213, which is used to visualise GABA_B receptors expressed in COS cells, is synthesised according to Scheme 1, using the following reagents and conditions:

(1) NaH, THF, rt, 3 h; 5-bromovaleronitrile, rt, 16 h; (2) Raney nickel, 4% NH₃ in EtOH, 45° C, 16 h; (3) *N*-ethoxy-carbonylphtalimide, Na₂CO₃, H₂O, CH₂Cl₂, rt, 5h; (4) Me₃SiCl, EtOH, CH₂Cl₂ (1:9), rt, 17 h; (5) Me₃SiCl, Et₃N, THF, rt, 17 h; (*R*)-epichlorohydrin, 10 mol% ZnCl₂ THF, 80° C, 17 h; HOAc, MeOH, rt, 17 h; (6) *i*-Pr₂EtN, EtOH, 80° C, 7 d; (7) LiOH, EtOH, H₂O (1:1), 100° C, 17 h; MeOH, H₃PO₄; (8) conc. HCl, 100° C, 17 h; (9) *i*-Pr₂EtN, DMF, rt, 72 h; (10) Na¹²⁵I, phosphate buffer pH 7.4, H₂O₂, cat. lactoperoxidase, 30 min, RP-HPLC.

Ethyl (1,1-diethoxyethyl)phosphinate **1**, prepared according to Frost, W., *et al. J. Med. Chem.* (1995), **38**, 3297-3312, from phosphinic acid and triethylorthoacetate under catalysed by boron trifluoride diethyl etherate, is condensed with 5-bromovaleronitrile to give the oily cyano-derivative **2** (bp 164° C at 0.13 mbar), which is hydrogenated over Raney nickel in ethanol containing 4% of ammonia to give primary amine **3** (bp 150-160° C at 10⁻⁴ mbar; Kugelrohr bath temperature). The amino-group in **3** is protected as phthalimide to give **4**, which is now deprotected at the phosphinic acid moiety under very mild conditions to give monosubstituted phosphinic acid ester **5**. On reaction with trimethylchlorosilane the pentavalent phosphinate ester **5** is converted into a very reactive silylated phosphonite, which reacts readily with (*R*)-epichlorohydrin under zinc chloride catalysis to produce chlorohydrin **7**. Condensation with 1-(*R*)-(+)-(3-cyanophenyl)-ethylamine **8**, which itself is prepared via resolution of racemic (3-cyano-phenyl)-ethylamine with *N*-acetyl-*L*-leucine to separate 1-(*S*)-(+)-(3-cyanophenyl)-ethylamine (according to Pickard *et al.*, *J. Amer. Chem. Soc.* (1990) **112**, 5741-5747) and treatment of the remaining mother liquors with (-)-camphanic acid followed by three crystallisations, gives the aromatic nitrile-ester **9**, which is hydrolysed to the *meta*-benzoic acid derivative **10** with lithium hydroxide. Concomitant hydrolysis of the ethyl phosphinate ester occurs. The phthalimide protecting group is removed by boiling with concentrated hydrochloric acid overnight to give the key intermediate **CGP 57604A** ([3-[1-(*R*)-[3-(5-aminopentyl)-hydroxyphosphinyl]-2-(*S*)-hydroxypropyl]amino]-ethyl]-benzoic acid hydrochloride). This is reacted with commercially available *N*-hydroxysuccinimidyl-3-(4-hydroxyphenyl)-propionate **11** in DMF using Hünig's base to give intermediate **12**, which is iodinated with sodium iodide (125 isotope) using hydrogen peroxide and catalytic amounts of lactoperoxidase to give the radioactive ligand [¹²⁵I]**CGP 64213**.

Schem 1

Unlabelled **CGP 64213** is prepared in a slightly different way: 3-(4-hydroxy-5-iodophenyl)propionic acid **13** is prepared by iodination of 3-(4-hydroxy-phenyl)propionic acid according to Runeberg, J., *Acta Chem. Scand.* (1958), 12, 188-91. *N*-hydroxy-succinimidyl-3-(4-hydroxy-5-iodophenyl)propionate **14** (mp: 191-4° C) is prepared according to Scheme 2 in 73% yield. Condensation of **CGP 57604A** (Scheme 1) with **14** using Hünig's base in DMF at room temperature for 72 hours proceeded as reaction 9 of Scheme 1 to give non radioactive **CGP 64213** (mp: 170-5° C, crystallised from acetone) in a yield of 53%.

Scheme 2^a

^a Reagents and conditions: *N*-hydroxysuccinimide, DCC, dioxane, rt, 16 h.

Characterisation of radioligand [¹²⁵I]CGP 64213:

Preparation of synaptic membranes from rat cerebral cortex

Twenty male rats [Tif: RAI f (SPF)] of about 200 g body weight are used. The animals are decapitated, the brains removed, the cerebral cortices dissected and homogenised in 10 volumes of ice-cold 0.32 M sucrose, containing MgCl₂ (1 mM) and K₂HPO₄ (1mM), with a glass/Teflon homogeniser. The membranes are centrifuged at 1000 x g for 15 min, the pellet resuspended and the centrifugation repeated. The supernatants are pooled and centrifuged at 20000 x g for 15 min. The pellet is osmotically shocked by resuspension in 10 volumes H₂O and kept on ice for 30 min. The suspension is centrifuged at 39000 x g, resuspended in Krebs-Henseleit buffer (20mM Tris, pH 7.4, 118mM NaCl, 5.6mM glucose, 1.2mM KH₂PO₄, 1.2mM MgSO₄, 4.7mM KCl, 1.8mM CaCl₂), and kept for 2 days at -20°C. The membranes are thawed at room temperature, washed three times with Krebs-Henseleit buffer by centrifugation at 20000 x g for 15 min, left overnight at 4°C and washed again three times. The final pellet is resuspended with a glass/Teflon homogenise in 20 ml of the same buffer. 2 ml aliquots are frozen and stored in liquid nitrogen. Just before use membranes are thawed quickly in a water bath at 37°C and again washed by centrifugation at 20000 x g for 15 min with the same buffer three times.

Binding assay and characterisation of radioligand

Incubation with [¹²⁵I]CGP 64213, specific radioactivity for fresh material 2000 Ci/mmol, is performed in 0.2 ml Krebs-Henseleit-Tris buffer, pH 7.4, at 20°C for 90 min with 50 µg cortex membrane protein as substrate. The incubation is terminated by filtration through GF/B Whatman glass fibre filters. Nonspecific binding is defined by 10⁻⁶ M CGP 54626A and is 5% of total binding at a concentration of 2 nM. In saturation experiments with increasing concentrations of [¹²⁵I]CGP 64213 and with nonlinear least square fitting a dissociation constant K_D of 2.66 nM is determined. In inhibition studies at a concentration of 0.1 nM [¹²⁵I]CGP 64213, L-baclofen showed an inhibition constant K_i of 442 nM and the antagonist CGP 54626 A a K_i of 2.5 nM in good agreement with K_i's obtained with other GABA_B receptor antagonist radioligands. Unlabelled CGP 64213 is found to be inactive at a concentration of 1 µM in assays for GABA_A, benzodiazepine, kainate, AMPA, NMDA receptors, for the strychnine independent binding site at NMDA receptors, muscarinic cholinergic, α₁- and α₂-adrenergic, β-adrenergic, 5HT₁, 5HT₂, 5HT₃, histamine₁, histamine₂, adenosine, µ-opiate and substance P receptors. The compound is therefore selective for GABA_B receptors. At a concentration of 0.1 nM of [¹²⁵I]CGP 64213 association and dissociation kinetics are measured. The halftime of association is 20 min at 20°C and the halftime of dissociation 40 min. The halftime of dissociation is increased to 4 hours by reduction of the temperature to 4°C. This slow off rate and the high specific radioactivity of [¹²⁵I]CGP 64213 allows autoradiographic studies of receptor binding in COS cells as expression systems for GABA_B receptors.

Example 2**Preparation of photoaffinity ligand**

The photoaffinity ligand [¹²⁵I]CGP 71872, which is used to tag GABA_B receptors from rat cortex membranes and recombinant GABA_B receptors expressed in COS cells is synthesised according to Scheme 3: Commercially available *N*-hydroxy-succinimidyl-4-azido-salicylate 15 is condensed with CGP 57604A to give intermediate 16, which is iodinated with sodium iodide 125 isotope using chloramine T to give an approximately 1:1 mixture of the 5-iodo derivative [¹²⁵I]CGP 71872 and the 3-iodo-derivative [¹²⁵I]CGP 72565. They are separated via reverse phase HPLC on a Vydac 218TP54 column (retention times: 16.4 and 17.4 minutes, respectively). Reagents and conditions are as follows:

(1) **CGP 57604A** (Scheme 1), $i\text{-Pr}_2\text{EtN}$, DMF, rt, 70 h; (2) Na^{125}I , chloramine T, 0.01 N NaOH, rt, 1 h; RP-HPLC.

Scheme 3

Unlabelled **CGP 71872** is prepared in a different way: *N*-hydroxy-succinimidyl-4-azido-5-iodo-salicylate **17** is prepared via iodination of 4-azidosalicylic acid and subsequent condensation with *N*-hydroxy-succinimide (Scheme 4). Condensation of **17** with **CGP 57604A** (see Scheme 1, reaction 9) proceeded in 57 % yield to give non radioactive **CGP 71872** (mp: $>190^\circ\text{C}$ dec.).

Reagents and conditions as follows: (1) (1) NaI, 2N NaOH, chloramine T, rt, 88 h; (2) *N*-hydroxysuccinimide, DCC, dioxane, rt, 16 h;

Scheme 4

Characterisation of high affinity ligand [125 I]CGP 71872:

Binding assay and characterisation of ligand

Rat cortex membranes as described for the [125 I]CGP 64213 assay are used as substrates. Incubation with [125 I]CGP 71872, specific radioactivity of fresh material 2000 Ci/mmol, is performed in 0.2 ml Krebs-Henseleit buffer, pH 7.4, at 20°C for 90 min with 50 μ g membrane protein as substrate. The incubation is terminated by filtration through GF/C Whatman glass fibre filters. Nonspecific binding is defined by 10^{-6} M CGP 54626 A and is 5% of total binding at a concentration of 2 nM of [125 I]CGP 71872. In saturation experiments with increasing concentrations of [125 I]CGP 71872, and nonlinear least square fitting a dissociation constant K_D of 3.1 nM is calculated. L-baclofen showed in inhibition experiments a K_i of 340 nM and the antagonist CGP 54 626 A showed a K_i of 3.1 nM. Unlabelled CGP 64213 is found to be inactive at a concentration of 1 μ M in the same receptor assays as described for [125 I]CGP 64213 and is, therefore, also selective for GABA $_B$ receptors. At a concentration of 2 nM and at 20°C, the half-time for association is 5 min, the half-time of dissociation 10 min. The dissociation time at 8°C is much longer. Only 25% of radioligand dissociates after 120 min.

Photoaffinity labelling of membranes

Membranes from rat cerebral cortex and from COS1 cells transiently transfected with GABA $_B$ R1a and GABA $_B$ R1b rat-cDNA, respectively, suspended in Krebs-Henseleit-Tris buffer, pH 7.3, at a concentration of 4 mg protein/ml, are incubated in the dark with 0.6 nM [125 I] CGP 71872 for one hour at room temperature. The incubation is terminated by centrifugation at 20 000 x g for 10 min at 4°C. This step removed free unbound photoaffinity label. Under these conditions about 50% of the total radioactivity used bound to the receptors. The pellet is resuspended at a concentration of 4mg protein/ml in a polyethylene vial and illuminated with UV light (365 nm) for 3 min (24 W). The suspension is centrifuged at 20 000 x g for 10 min and resuspended at a concentration of 8mg/ml protein in buffer. When the labelling is performed in the presence of excess unlabelled GABA $_B$ receptor antagonist (10^{-6} M CGP 54626A), no radioactivity is bound to the membranes. The labelled membranes could be stored at -80°C. The results are shown in Figures 1a and 1b.

Additionally, [125 I]CGP71872 photoaffinity labelling of cortex, cerebellum and spinal cord cell membranes is analysed as outlined above and reveals that the two GABA $_B$ protein variants R1a and R1b are differentially expressed in the nervous system. In cerebellum the

100K protein is predominant over the 130K protein, whereas in spinal cord the 130K protein is more prevalent. In cortex tissue both proteins appear equally abundant. No proteins are labelled in tissues such as liver and kidney which are expected to lack GABA_B receptors and therefore have been used as controls (see Figure 4a).

Furthermore, native GABA_B receptors are photoaffinity-labelled in the presence of various competitor substances indicated in Figure 4b. Neither the GABA_A selective ligands muscimol and bicuculline nor the GABA_C receptor agonist *cis*-aminocrotonic acid (CACA) or the inhibitor of the GABA uptake system, SK&F89976A (Zuiderwijk, M., Veenstra, E., Lopes Da Silva, F. H. & Ghijsen, W. E. J. M. Effects of uptake carrier blockers SK&F89976-A and L-*trans*-PDC on in vivo release of amino acids in rat hippocampus. *Eur. J. Pharmacol.* **307**, 275-282 (1996)), compete significantly for radioligand binding. In contrast, the GABA_B receptor agonists GABA, APPA (3-aminopropyl-phosphinic acid) and L-baclofen compete with [¹²⁵I]CGP71872 for binding. As another known criterion, L-baclofen competes more potently than D-baclofen. The GABA_B receptor antagonists CGP54626A, CGP35348 and the non-radioactive photoaffinity ligand are also effective displacers of [¹²⁵I]CGP71872 at native receptors. For all ligands tested, there is no visible difference in the displacement of [¹²⁵I]CGP71872 at the 130K and 100K proteins, indicating a qualitatively similar binding pharmacology for the two receptors.

Native GABA_B receptors are N-glycosylated, as shown by the reduction in molecular weight to 110K and 90K, respectively, after cleavage with N-glycosidase F (Fig. 4c). No significant shift in molecular weight is detected after enzymatic treatment with O-glycosidase (Fig. 4c). Photoaffinity-labelled proteins of 130K and 100K are detectable in tissues from all vertebrate species analysed, including zebrafish (Fig. 4d), indicating that the two proteins and their antagonist binding site are highly conserved. The avian GABA_B receptor proteins exhibit molecular weights slightly higher than in other species, possibly reflecting differences in glycosylation and/or RNA splicing. No binding of the photoaffinity ligand to any protein can be detected in the fruitfly *Drosophila melanogaster* and the nematode *Haemonchus contortus*.

Example 3

Synthesis of the GABA_B antagonist ligand CGP 54626A:

The ligand used for displacement experiments, CGP 54626A, is synthesised according to Scheme 5:

Scheme 5^a

^a Reagents and conditions: (1) NaH, THF, rt, 3 h; bromomethylcyclohexane, reflux, 24 h; (2) Me₃SiCl, EtOH, CH₂Cl₂ (1:9), rt, 24 h; (3) Me₃SiCl, Et₃N, THF, rt, 24 h; (R)-epichlorohydrin, 10 mol% ZnCl₂ THF, 80° C, 17 h; HOAc, MeOH, rt, 17 h; (4) *i*-Pr₂EtN, EtOH, 80° C, 7 d; (5) conc. HCl, 100° C, 24 h.

Ethyl (1,1-diethoxyethyl)phosphinate 1, prepared according to Froestl et al., *J. Med. Chem.* (1995), 38, 3297-3312, from phosphinic acid and triethylorthoacetate catalysed by boron trifluoride diethyletherate, is condensed with bromomethylcyclohexane to give the oily derivative 18 (bp 85° C at 6×10^{-4} mbar), which is deprotected at the phosphinic acid moiety under very mild conditions to give monosubstituted phosphonic acid ester 19 (bp 50° C at 3×10^{-4} mbar). On reaction with trimethylchlorosilane the penta-valent phosphinate ester 19 is converted into a very reactive trivalent ethyl phosphonite, which reacted rapidly with (R)-epichlorohydrin 6 when catalysed by zinc chloride to produce chlorohydrin 20. Condensation with 1-(S)-(-)-(3,4-dichlorophenyl)-ethylamine 21, prepared via resolution of racemic 1-(3,4-dichlorophenyl)-ethylamine with (+)-mandelic acid according to Mickel, EP 543780 A2, gave the corresponding secondary amine 22 as a 1:1 mixture of

diastereoisomers, which is hydrolysed by boiling with concentrated hydrochloric acid to give CGP 54626A.

[³H]CGP54626A is prepared in an analogous way (Scheme 6) by condensation of ethyl (1,1-diethoxyethyl)phosphinate 1 with 3,4-dehydro-cyclohexylmethylbromide (prepared according to Yadav and Fallis, (1991) *Can. J. Chem.* 69, 779-789), preparation of the corresponding 3,4-dehydroderivative of CGP 54626A, i.e. CGP 54951A, which is tritiated under very carefully controlled conditions to yield [³H]CGP54626A. The compound is the first GABA_B receptor antagonist radioligand which was characterised by Bittiger *et al.*, *Pharmacol. Commun.* (1992), 2, 23.

Scheme 6^a

^a Reagents and conditions: (1) NaH, THF, rt, 3 h; 3-4-dehydrobromo-methylcyclohexane, reflux, 24 h; (2) Me₃SiCl, EtOH, CH₂Cl₂ (1:9), rt, 24 h; (3) Me₃SiCl, Et₃N, THF, rt, 24 h; (R)-epichlorohydrin, 10 mol% ZnCl₂ THF, 80° C, 17 h; HOAc, MeOH, rt, 17 h; (4) *i*-Pr₂EtN, EtOH, 80° C, 4 d; (5) LiOH, EtOH, H₂O, 100° C, 17 h; HCl, MeOH, rt, 1 h; (6) ³H₂, 5% Pd/C, HCl, MeOH, pH = 1, rt, 15 min, prep. TLC.

Exempl 4**Proof of functional activity of CGP 64213 and CGP 71872 as GABA_B receptor antagonists by in vitro electrophysiological measurements.**

Experiments are performed on 400 µm thick hippocampal slices obtained either from female Wistar COB rats (3-4 weeks old) or male rats Tif: RAI f (SPF) using standard techniques. In brief, rats are cervically dislocated prior to decapitation. The brain minus cerebellum is removed rapidly and placed in ice-cold artificial cerebrospinal fluid (ACSF). The hippocampus is carefully isolated and, using either a tissue chopper (Sorvall) or a vibroslicer (Campden), transverse 400 µm thick slices are cut. The CA3 region of each slice is removed via a scalpel cut. This procedure is performed to eliminate changes in network function that can occur due to epileptiform bursting in area CA3. The resultant CA3-ectomized slices are placed on a nylon mesh at the interface of a warmed (32°C), perfusing (1-2 ml.min⁻¹) ACSF and an oxygen-enriched (95% O₂, 5% CO₂), humidified atmosphere. The standard perfusion medium comprised (mM): NaCl, 124; KCl, 3; NaHCO₃, 26; NaH₂PO₄, 1.25; CaCl₂, 2; MgSO₄, 1; D-glucose, 10; and is bubbled with 95% O₂, 5% CO₂. An Axoprobe or an Axoclamp-2 amplifier (Axon Instruments, Foster City, CA, USA) is used in bridge mode to make extracellular recordings from either *stratum radiatum* or *stratum oriens* using 4 M NaCl-filled microelectrodes (2 - 5 MΩ). Intracellular recordings are made using 2 M potassium methylsulphate filled microelectrodes (60-100 MΩ). Digitised records are stored on the hard disk of an IBM-compatible PC for off-line analysis. Bipolar stimulating electrodes, made from 55 µm diameter insulated nickel-chromium wire, are positioned in *stratum radiatum* close to the recording electrode placed in either *stratum radiatum* or *stratum oriens*, to provide orthodromic monosynaptic activation of CA1 neurones (Davies *et al.* (1990) *Journal of Physiology* 424: 513). In every experiment stimuli comprise square-wave pulses (20-200 µs; 5-30 V) delivered homosynaptically at a fixed intensity. All drugs are administered via the perfusion medium. Data are presented as means ± standard error of the mean (S.E.M.) and statistical significance is assessed using Students *t*-tests. *n* values refer to the number of times a particular experiment is performed, each in a different slice taken from a different rat.

GABA_B autoreceptors

Paired-pulse widening of field EPSPs is used to monitor the effects of CGP 71872 and CGP 64213 on GABA_B autoreceptors. Paired-pulse widening occurs when two stimuli

are delivered at 5-10 Hz (interstimulus interval 100 - 200 ms); a stimulation protocol that does not release sufficient GABA to activate GABA_B heteroreceptors which would, in any case, cause a depression rather than a facilitation of the second field EPSP. This phenomenon is also independent of postsynaptic GABA_B receptors (Nathan *et al.* (1991) *Exp. Brain Res.* **84**(3) 529-537). It is, however, occluded by blocking GABA_A receptor-mediated IPSPs and is inhibited by GABA_B receptor antagonists at concentrations that are required to block GABA_B autoreceptors (Nathan *et al.* (1990), *Brain Research* **531**: 55-65). (Note that these concentrations are 3-10 fold higher than those necessary to block postsynaptic GABA_B receptors on both pyramidal neurones and inhibitory interneurons so ruling out an effect at these receptors). Paired-pulse widening of field EPSPs (fEPSPs) is a sensitive measure of GABA_B autoreceptor activity. There is no precedent for any compound being effective in this test system and not in other assays of GABA_B autoreceptor activity e.g., paired-pulse or (-)-baclofen-induced depression of IPSCs.

Paired-pulse stimulation at an interstimulus interval of 200 ms caused a consistent widening of the second EPSP relative to the first EPSP. Thus, the area under the curve of the second fEPSP is $247 \pm 17 \%$ (in the CGP 64213 series of experiments) and $241 \pm 21 \%$ (in the CGP 71872 series of experiments) of the first fEPSP, respectively. In the presence of CGP 64213 (0.3 μ M; n = 5) and CGP 71872 (1 μ M; n = 3) this paired-pulse widening of EPSPs is abolished indicating the effectiveness of these compounds as antagonists of GABA_B autoreceptors.

GABA_B heteroreceptors

The effect of CGP 71872 on the depression of field EPSPs induced by bath application of (-)-baclofen is used as an assay for the effect of this compound on GABA_B heteroreceptors located on glutamate afferent terminals. Although, under these conditions, (-)-baclofen will activate other populations of GABA_B receptors (e.g., GABA_B autoreceptors and postsynaptic GABA_B receptors), in addition to GABA_B heteroreceptors, activation of these receptors would tend to increase the size of the field EPSP rather than decrease it. As such, this method is a reasonable measure of activity at GABA_B heteroreceptors. This method provides a more reliable and a quantitatively more repeatable method for activating GABA_B heteroreceptors than that used by Isaacson *et al.* (1993) *Neuron* **332**: 156-158, as it does not rely on physiologically released GABA to activate the heteroreceptors. This latter method is inherently variable due to the different concentrations of synaptically released

GABA to which heteroreceptors are exposed in different preparations; a parameter that depends upon the level of GABA released, the distance between the release site and heteroreceptor, and the efficiency of GABA uptake sites. It is important to note, however, that, to date, no discrepancy between the results obtained using these two methods to study GABA_B heteroreceptors has been documented for any compound tested.

(-)-Baclofen (10 μ M) had no significant effect on the presynaptic fibre volley of the field EPSP ($100 \pm 1\%$ of control; $P > 0.05$), recorded in *stratum radiatum*, but depressed the field EPSP slope and peak amplitude by $65 \pm 6\%$ and $76 \pm 9\%$, respectively ($n = 10$). Maximum depression is obtained after a 5-10 min perfusion and persisted at this level for the duration of the agonist application. Addition of CGP 71872 (1 μ M) to the perfusion medium reversed the depression in every experiment in which it is tested ($n = 6$; $P < 0.05$). Similar results are obtained for field EPSPs recorded in *stratum oriens* ($n = 3$). In brain slices CGP 71872 had no significant effect on the peak amplitude, slope or presynaptic fibre volley of field EPSPs recorded in *stratum radiatum* ($n = 4$; $P > 0.05$) or *oriens* ($n = 3$).

Postsynaptic GABA_B receptors

The effect of CGP 71872 on the pharmacologically isolated late IPSP is used as a test system to evaluate the effect of CGP 71872 on postsynaptic GABA_B receptors located on CA1 pyramidal neurones. There is a substantial literature (Froestl et al. (1995) *Op. Cit.*; Jarolimek et al. (1993) *Neurosci. Lett.* 154: 31-34; Olpe et al. (1990) *Clin. Neuropharmacol.* 13 Suppl. 2: 396; McCormick, (1990) *J. Neurophysiol.* 62/5: 1018; Lambert et al., (1989) *Neurosci. Lett.* 107: 125-128; Soltesz et al., (1989) *Brain Research* 479: 49-55; Mueller and Misgeld, (1989) *Neurosci. Lett.* 102: 229-234; Dutar and Nicoll, (1988) *Nature* 322: 156-8; Karlsson, Pozza and Olpe, (1988) *Eur. J. Pharmacol.* 148: 485-486) which indicates that this IPSP is mediated by the synaptic activation of GABA_B receptors. In addition, this method has been used many times in the past and the data generated have always been consistent with that generated for antagonism of (-)-baclofen-induced hyperpolarisations; an approach that has also been adopted as an assay for activity at postsynaptic GABA_B receptors.

The effect of CGP 71872 is tested on a monosynaptically activated GABA_B receptor-mediated late IPSP isolated using a combination of the ionotropic excitatory amino acid antagonists D-2-amino-5-phosphonopentanoate (AP5; 50 μ M) and 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 20 μ M) and the GABA_A receptor antagonist picrotoxin

(50 μ M). In all neurones tested CGP 71872 (1 μ M) abolished the late IPSP ($n = 6$) indicating that this compound is an antagonist of postsynaptic GABA_B receptors.

Example 5

cDNA library construction

RNA is purified from cortex and cerebellum of 7 day old rats according to Chomczynski, P. & Sacchi, N. (1987) *Anal. Biochem.* 162, 156-159. Poly A(+) RNA is enriched by two passages over an oligo (dT) column (Boehringer Mannheim) as described (Maniatis, T., Fritsch, E.F. & Sambrook, J. (1982) *Molecular cloning: A laboratory manual* (Cold Spring Harbor Lab., Cold Spring Harbor, NY). Oligo (dT) primed double stranded cDNA is synthesised from 5 μ g of poly A(+) RNA using a commercial cDNA synthesis system (Amersham). The reverse transcriptase supplied with the kit is replaced by the RNaseH(-) Superscript II reverse transcriptase (Gibco BRL). The cDNA solution is concentrated on Centricon-100 devices (Amicon), preabsorbed with tRNA, to a final volume of 100 μ l. Small cDNAs are removed by passage through a Chromaspin-1000 column (Clontech). BstXI adaptors (Invitrogen) are added using T4 DNA ligase (Boehringer Mannheim) and the cDNAs are size-fractionated on an agarose gel. cDNAs with sizes larger than 2kb are purified (Qiaex, Qiagen) and ligated into the BstXI sites of the expression vector pcDNA1 (Invitrogen). An aliquot of the ligation mixture is transformed (BioRad Gene Pulser II) into electrocompetent MC1061/P3 E.coli cells. The complexity of the library is estimated to be 2×10^6 independent clones. The average insert size deduced from the analysis of 48 clones is 2.9kb (sizes ranging from 2.0kb to 6.6kb).

Plasmids for the transfections of COS1 cells are isolated from bacterial colonies obtained after the initial round of cDNA transformation. Briefly, an aliquot of the cDNA library is transformed into electrocompetent MC1061/P3 E.coli cells and titrated by plating on agar plates. The cDNA library is divided into pools of approximately 2'000 colonies that are plated on 9cm agar plates and grown overnight at 37°C. The bacteria are scraped off the plates and plasmid DNA is prepared using ion exchange columns (Qiawell, Qiagen).

Example 6**Transfection of COS cells with DNA**

COS1 cells are obtained from the American Type Culture Collection (ATCC) and grown in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% fetal calf serum (FCS) and 15µg/ml gentamycin (Gibco BRL) in a humidified atmosphere with 5% CO₂.

Plasmid DNA from pools of independent bacterial colonies are introduced into COS1 cells using a modification of the standard DEAE-dextran transfection procedure. Briefly, one day before transfection 7.5×10^5 cells are seeded per 9cm dish. The next day the medium is removed and the cells are incubated 15 min in 10ml of phosphate buffered saline (PBS tablets, Gibco BRL). Afterwards, PBS is removed and 4ml of 1mg/ml DEAE-dextran (Pharmacia) in PBS is added to the dish. After 9 min incubation at room temperature the cells are washed twice with 5ml of PBS each. The PBS is aspirated and 4µg plasmid DNA (derived from pools of 2'000 independent bacterial colonies) in 540µl PBS is added to the dish and the cells incubated with the DNA for 30 min at 37°C with occasional rocking. Subsequently 4ml of DMEM medium containing 10% NU-serum (Collaborative Research) and 80µM chloroquine (Sigma) is added. After 4 hrs incubation at 37°C the medium is removed and the cells are incubated 2 min in 10% (vol/vol) dimethyl sulfoxide (Merck) in PBS. The cells are rinsed with PBS, cell culture medium is added to the culture dishes and the cells are grown for an additional 2 to 3 days.

Example 7**Identification of GABA_B receptor clone by ligand binding assay**

Pools of cDNAs (2000 independent clones each) are analysed for GABA_B receptor expression, after transient transfection into COS1 cells, using a radioligand binding assay with iodinated CGP64213 (specific activity 2'000 Ci/mmol).

Culture dishes with transfected COS1 cells are placed on ice and washed twice with 5ml each of ice-cold Krebs-Henseleit-Tris buffer (20mM Tris-Cl pH 7.4, 118mM NaCl, 5.6mM glucose, 1.2mM KH₂PO₄, 1.2mM MgSO₄, 4.7mM KCl, 1.8mM CaCl₂). Afterwards the cells are incubated with 0.2nM of ¹²⁵I-CGP 64213 in Krebs-Tris buffer (1ml solution per 9cm dish). After 80 min incubation at room temperature the dishes are cooled on ice and washed twice for 5 min with 5ml of ice-cold Krebs-Tris buffer. Subsequently the dishes are

air dried using a fan and the walls of the plates are removed. For autoradiography, the bottom of the plates are exposed, together with intensifying screens, to Kodak X-OMAT AR films for 2 to 3 weeks at -80°C.

A total of 640,000 independent clones (320 individual pools) from the above mentioned cDNA library are screened. One pool yields a positive signal in the ligand binding assay. The plasmid DNA from this pool is re-transformed into electrocompetent MC1061/P3 cells. 10 plasmid pools from 500 colonies each are prepared, two of which rescreened positive in the binding assay. After 4 subsequent rounds of subdivisions of one of the two pools (SIB selection; McCormick, M. (1987) *Methods Enzymol.* **151**, 445-449) a single cDNA clone containing a 4376bp insert is identified. This first cDNA clone identified, originally referred to as F4, is designated GABA_BR1a (SEQ ID No. 1). This cDNA clone encompasses a large open reading frame coding for a putative protein of 960 amino acids with a calculated molecular weight of 108kDa (SEQ ID No.2). According to von Heijne (von Heijne, G. (1986) *Nucl. Acids. Res.* **14**, 4683-4691) the first 16 amino acids encode with high probability a signal peptide that is absent in the mature protein. The calculated molecular weight of the predicted mature protein is 106kDa. Hydrophobicity analysis of the putative protein with the algorithm of Kyte and Doolittle (1982) *J. Mol. Biol.* **157**, 105-132, using sequence analysis programs from the University of Wisconsin Genetics Computer Group (Devereux, *et al.*, (1984) *Nucl. Acids. Res.* **12**, 387-395) predicts, as expected for a cell surface receptor coupled to G-proteins, several membrane spanning regions. Putative N-glycosylation sites are found at amino acid positions 7, 67, 392, 423, 465, 485, 497 and 614 of the predicted mature protein as set forth in SEQ ID No. 2.

Example 8

Assay of cloned GABA_B receptor

In order to isolate membranes containing the cloned GABA_B receptor, culture dishes containing GABA_B receptor-expressing COS cells are washed twice with Krebs-Henseleit-Tris buffer. Afterwards the cells are scraped off the dishes, homogenised in a glass-glass homogeniser and centrifuged for 30 min at 4°C at 40'000 g. The homogenisation and centrifugation step is repeated once. The pellet is resuspended in buffer and stored in liquid nitrogen until further analysis.

Membranes from COS1 cells transfected with the GABA_B receptor cDNA (membranes derived in a similar manner from brain tissue are used for reference) are suspended in Krebs-Henseleit-Tris buffer at a concentration of approximately 1 mg/ml. The membranes are then incubated in the dark with 0.6 nM [¹²⁵I]-CGP 71872 for one hour at room temperature. In control experiments 1 μM of unlabeled CGP 54626A, a GABA_B receptor specific antagonist, is included. The incubation is terminated by centrifugation at 20'000 g for 10 min at 4°C. The pellet is washed once in buffer to remove unbound from bound photoaffinity label. The pellet is resuspended in buffer and illuminated with UV light (365 nm, 24 W) for 3 min. The suspension is again centrifuged (20 min, 40'000 g). The pellet is washed in buffer, dissolved in SDS sample buffer and separated on a 6% SDS gel according to Laemmli, U.K (1970) *Nature* 227, 680-685. The gel is dried and, together with intensifying screens, exposed to Dupont Reflection NEF-495 X-ray films overnight. The protein expressed from the 4'376 bp cDNA clone has an apparent molecular mass of about 120 kDa (Figure 1). The apparent molecular weight of the recombinant GABA_B receptor is estimated from gel mobility relative to those of SDS-PAGE standards (BioRad).

The binding pharmacology of the GABA_BR1a receptor expressed in COS1 cells is compared with the binding pharmacology of native GABA_B receptors in rat cerebral cortex membranes. To that aim, the binding characteristics of the radioligand [¹²⁵I]CGP 64213 and the inhibition of this binding by selected GABA_B receptor antagonists and agonists are compared. The dissociation constant K_D for the GABA_BR1a receptor expressed in COS cells is determined to be 1.85 nM. The K_D of GABA_B receptors expressed in cortex membranes is determined to be 2.7 nM and thus is similar to the value obtained for the recombinant receptor. The IC₅₀ values (Table 1) and the slopes of the inhibition curves (Figure 2) for the GABA_B receptor antagonists CGP 54626A (Froestl *et al.*, (1992) *Pharmacol. Communications* 2, 52-56), CGP 71872, CGP 64213 and CGP 35348 (Froestl *et al.*, 1992) are very similar for recombinant and native receptors. The rank order of affinity for the agonists GABA, L-baclofen and CGP 27492 (aminophosphinic acid, APPA) is identical at recombinant and native receptors, however the agonist affinity is always significantly lower at the recombinant GABA_BR1a receptor (Figure 3, Table 1). It is known that GTP or its stable analogue Gpp(NH)p reduce the affinity of agonists at native GABA_B receptors by decoupling the receptors from their G-proteins (Hill *et al.*, (1984) *J. Neurochem.* 42, 652-657). Therefore, the lower affinity of agonists at the recombinant receptor may reflect the fact that in COS cells the G-proteins that normally couple to GABA_B receptors in brain cells

are not available. We have determined that for rat cortex GABA_B receptors the IC₅₀ value of L-baclofen is shifted from 170 nM to 10 μ M in the presence of 300 μ M Gpp(NH)p. Thus decoupling G-proteins from native GABA_B receptors results in an IC₅₀ value comparable to the 34 μ M obtained for the recombinant GABA_BR1a receptor expressed in COS cells. In conclusion, the recombinant GABA_BR1a receptor shows similar binding pharmacology as native GABA_B receptors from rat cortex.

Table 1. BINDING PHARMACOLOGY OF NATIVE AND RECOMBINANT GABA_B RECEPTORS

Inhibition of [¹²⁵I]CGP 64213 binding by GABA_B receptor antagonists and agonists

| ANTAGONISTS | <i>Rat cerebral cortex</i> | <i>COS1 cells</i> |
|-------------|-----------------------------|-----------------------------|

| CGP 47656 (partial agonist) | 0.28 | 12.3 |

Exempl 9**Use of the GABA_BR1a receptor cDNA to clone related genes**

The rat GABA_BR1a-receptor cDNA isolated (SEQ ID No. 1) is useful as a probe to identify and isolate additional cDNAs, genes and proteins of the GABA_B-receptor gene family. It is also useful to identify and isolate cDNAs, genes and proteins of the GABA_B-receptor gene family in other species, such as for example humans.

In order to isolate a further rat clone (referred to as GABA_BR1b) and human GABA_B receptor clones, the abovementioned rat library and a human fetal brain cDNA library (Clontech, Palo Alto, cat. No. HL3025s) are cross-hybridised with the GABA_BR1a cDNA under suitable hybridisation conditions. The human library is an unidirectional oligo (dT)-primed library consisting of 1.2×10^6 independent cDNA clones inserted into the expression vector pcDNAI. The method of screening a plasmid library by colony hybridisation is described in Sambrook et al. (1989). The hybridisation probe used is a ³²P-labelled 1.3kb PvuII/Scal fragment corresponding to bases 1931 to 3264 of the GABA_BR1a cDNA (SEQ ID No. 1). Hybridisation is in 0.5M NaH₂PO₄ (pH 7.2), 7% SDS, 1mM EDTA at 60°C overnight. Subsequent wash steps are for one hour at a final stringency of 0.5 x SSC, 0.1% SDS at 55°C (rat library) or 2 x SSC, 0.1% SDS at 50°C (human library). Kodak X OMAT AR films are exposed to the membranes overnight at -80°C with intensifying screens. The X-ray films are aligned to the agar plates with the bacterial colonies and colonies containing cross-hybridising cDNA clones are isolated. The bacteria are replated on agar dishes and the colony hybridisation screen is repeated twice. The individual colonies obtained are further analysed by Southern blot hybridisation. Selected cDNA clones are analysed by sequencing and a 2,9 kb cDNA for rat GABA_BR1b characterised (see SEQ ID No. 5). This cDNA encodes a protein of 844 amino acids (see SEQ ID No. 6). The mature GABA_BR1b differs from the former GABA_BR1a in that the N-terminal 147 amino acid residues are replaced by 18 different residues. Presumably, these two GABA_B receptor variants are derived from the same gene by alternative splicing. Those clones which are positive in screening the human library are also analysed by sequencing and reveal one clone termed GABA_BR1a/b (see SEQ ID No. 3) with a partial sequence encoding a receptor protein of 793 amino acid residues (see SEQ ID No. 4), as well as another clone termed GABA_BR1b human (see SEQ ID No. 7) which represents a full-length cDNA encoding a human GABA_B receptor having 844 amino acids (see SEQ ID No. 8).

Example 10**GABA_B receptors stably expressed in HEK293 cells negatively couple to adenylate cyclase**

GABA_B receptors are described to inhibit adenylate cyclase activity, stimulate phospholipase A₂, activate K⁺-channels, inactivate voltage-dependent Ca²⁺-channels and to modulate inositol phospholipid hydrolysis. As GABA_BR1a and -b have identical sequence in all domains predicted to be intracellular they are expected to be able to couple to the same effector systems. Using rat cortical slice preparations, L-baclofen has been shown to reduce forskolin-stimulated cAMP accumulation by about 40 percent. The ability of GABA_BR1a stably expressed in HEK293 cells to reduce forskolin-stimulated cAMP accumulation is analysed (Fig. 5). We chose concentrations of forskolin and L-baclofen that should produce a maximal effect. Forskolin stimulates cAMP levels in HEK293 cells to more than ten times over the basal level. Stimulation of recombinantly expressed GABA_B receptors by co-addition of 300 µM L-baclofen reduces forskolin stimulated cAMP accumulation by approximately 30 percent. This inhibition is antagonised by CGP54626A, a GABA_B receptor antagonist. The modulation of adenylate cyclase activity by GABA_BR1a is sensitive to pertussis toxin, indicating that in HEK293 cells, which are deficient in G_O, GABA_BR1a couples to G_i. As a control, L-baclofen does not inhibit forskolin-stimulated cAMP formation in untransfected HEK293 cells (Fig. 5).

Deposition Data

The GABA_B receptor clone GABA_BR1a derived from rat was deposited under the Budapest Treaty at the Deutsche Sammlung von Microorganismen und Zellkulturen GmbH (DSMZ), Mascheroder Weg 1b, D-38124 Braunschweig, Germany, with an effective deposition date of 17th May 1996 under the accession number DSM 10689.

The GABA_B receptor clones GABA_BR1b derived from rat as well as GABA_BR1b derived from human sources were deposited under the Budapest Treaty at the Deutsche Sammlung von Microorganismen und Zellkulturen GmbH (DSMZ), Mascheroder Weg 1b, D-38124 Braunschweig, Germany, with an effective deposition date of 21th February 1997 under the accession numbers DSM 11422 and 11421, respectively.

(2) INFORMATION FOR SEQ ID NO: 7:

(i) SEQUENCE CHARACTERISTICS:

- (A) LENGTH: 2924 base pairs
- (B) TYPE: nucleic acid
- (C) STRANDEDNESS: double
- (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA to mRNA

(iii) HYPOTHETICAL: NO

(iv) ANTI-SENSE: NO

(vi) ORIGINAL SOURCE:

- (A) ORGANISM: Homo sapiens

(vii) IMMEDIATE SOURCE:

- (B) CLONE: GABABR1b human

(ix) FEATURE:

- (A) NAME/KEY: CDS

- (B) LOCATION: 169..2700

(ix) FEATURE:

- (A) NAME/KEY: mat_peptide

- (B) LOCATION: 169..2700

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 7:

- 94 -

What is claimed is:

1. A purified GABA_B receptor or receptor protein.
2. A GABA_B receptor or receptor protein according to claim 1 which is capable of specific binding to at least one of the selective GABA_B receptor antagonists of Formulae I or II:

3. A GABA_B receptor or receptor protein according to claim 1 which is encoded by any one of the nucleic acid sequences set forth in the group consisting of SEQ ID No. 1, SEQ ID No. 3, SEQ ID No. 5 and SEQ ID No. 7, or by a nucleic acid clone selected from the group consisting of clones deposited at the DSMZ under accession numbers DSM 10689, DSM 11421 and DSM 11422.
4. A GABA_B receptor or receptor protein according to claim 1 having substantial homology to any one of the amino acid sequences set forth in the group consisting of SEQ ID No. 2, SEQ ID No. 4, SEQ ID No. 6 and SEQ ID No. 8.
5. A GABA_B receptor or receptor protein according to claim 1 which is a human GABA_B receptor or receptor protein.

- 95 -

6. A GABA_B receptor or receptor protein according to claim 5 having substantially the same amino acid sequence as set forth in SEQ ID No. 8.
7. An isolated nucleic acid encoding a GABA_B receptor or receptor protein.
8. A method for identifying a nucleic acid encoding a GABA_B receptor or receptor protein, comprising the steps of:
 - preparing an expression library encoding cDNA molecules which potentially encode a GABA_B receptor or receptor protein;
 - screening the expression library with a specific ligand capable of binding to a GABA_B receptor or receptor protein; and
 - isolating the cDNA clone encoding a GABA_B receptor or receptor protein.
9. A method for identifying a nucleic acid encoding a GABA_B receptor or receptor protein, comprising the steps of:
 - preparing a library encoding cDNA or genomic DNA molecules which potentially encode a GABA_B receptor or receptor protein;
 - screening the library by hybridisation with a nucleic acid probe which is capable of hybridising to any one of the nucleic acid sequences set forth in the group consisting of SEQ ID No. 1, SEQ ID No. 3, SEQ ID No. 5 and SEQ ID No. 7; and
 - identifying the nucleic acid molecules which hybridise to the probe.
10. A method for screening compounds or mixtures of compounds which are potential modulators of GABA_B receptor activity, comprising the steps of:
 - preparing a test system comprising a recombinant GABA_B receptor or receptor protein;
 - exposing the test system to the compound or mixture of compounds;
 - identifying the compound or mixture of compounds which causes modulation of GABA_B receptor activity as measured by the test system.
11. A method for screening compounds or mixtures of compounds which are potential modulators of GABA_B receptor expression, comprising the steps of:
 - providing an expression system comprising a test gene operably linked to control sequences normally associated with a gene encoding a GABA_B receptor or receptor protein;

- 96 -

identifying the compounds which cause a change in the level of expression of the test gene.

12. A nucleic acid complementary to the nucleic acid of claim 7.
13. A nucleic acid probe which is capable of hybridising to any one of the nucleic acid sequences set forth in the group consisting of SEQ ID No. 1, SEQ ID No. 3, SEQ ID No. 5 and SEQ ID No. 7, under conditions of low stringency.
14. A nucleic acid according to claim 13 which is an antisense nucleic acid.
15. A method according to claim 8 wherein the specific ligand is the compound of Formula I or the compound of Formula II.
16. A replicable nucleic acid vector comprising a coding sequence consisting of a nucleic acid according to claim 7 operably linked to suitable control sequences.
17. A host cell transformed with a vector according to claim 16.
18. An antibody specific for GABA_B receptor or receptor protein.
19. A transgenic non-human mammal which has been modified to modulate the expression of GABA_B receptor or receptor protein.
20. The selective GABA_B receptor antagonist of Formula I.
21. The selective GABA_B receptor antagonist of Formula II.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/EP 97/01370

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C12N15/12 C07K14/705 C07K16/28 G01N33/68 C07F9/30
C12N15/11 A01K67/027

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 C07K C07F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category * | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
|------------|---|-----------------------|
| P,X | KAUPMANN K ET AL: "Expression cloning of GABA(B) receptors uncovers similarity to metabotropic glutamate receptors [see comments]" NATURE, MAR 20 1997, 386 (6622) P239-46, ENGLAND, XP002032306 & Comment in Nature 1997 Mar 20;386(6622)223-224 see the whole document | 1-18 |
| X | NAKAYASU H ET AL: "Immunoaffinity purification and characterization of gamma-aminobutyric acid (GABA)B receptor from bovine cerebral cortex." J BIOL CHEM, APR 25 1993, 268 (12) P8658-64, UNITED STATES, XP002032307 see the whole document | 1,5,10, 11,18 |

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search

10 June 1997

Date of mailing of the international search report

25. 09. 97

INTERNATIONAL SEARCH REPORT

International application No.

PCT/EP 97/ 01370

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. Claims 1-18 :A GABA_A receptor, sequence encoding said receptor. Expression vector and recombinant host cells for the production of GABA_A receptor. Screening for ligands of the GABA_A receptor. Antibodies immunoreactive with GABA_A receptor 88-2B Transgenic non-human mammal expressing said receptor.
2. Claims 19,20 :GABA_A receptor antagonists.

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-18

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
